ABSTRACT
Insects are exotic alternative protein source with high nutritional value and limited environmental footprint. The aim of this study is to explore the colour characteristics, technological and sensory properties of sponge cakes enriched with cricket 5% and 10% cricket flour (CF5C and CF10C), used as substitute of the wheat flour. Moisture, pH, aw, springiness and specific volume decrease with increasing CF in a dose depend manner. Replacement of 10% cricket flour showed negative effect on the colour characteristics, shrinkage, specific volume, springiness and texture of sponge cakes. In CF10C a* shows highest values, while L* and b* present the lowest indications in comparison to other samples measured. The sensory panel found nonspecific taste and off-flavour in 10% CF based sponge cakes. Replacement of wheat flour with up to 5% CF has slight effect on the sensory properties (appearance, cell size uniformity, crumb tenderness, odour and taste) of sponge cakes and can successfully be used as innovative ingredient to enhance the protein content in bakery products.

Edible insects;
Insect based products;
Color characteristics.

1.Introduction
Pastries are most often made from wheat flour and are characterized by small amount of natural bioactive components. This leads to trade-offs in the quality of the finished product in terms of nutrition and health. The use of dietary fibres from various sources partially replaces wheat flour and contributes to the added value to those products (Anonymous, 2001).

Nowadays, food industry pays increasing attention to insects and insect flours as an alternative protein source with high nutritional value. Some beneficial aspects of insect usage are the significant content of protein, vitamins, and minerals and limited environmental footprint (Smarzyński et al. 2019). Insect consumption in Africa, Australia and Latin America has a long history (Melgar - Lalanne et al., 2019). Cricket flour (Acheta domesticus) is a good source of protein (da Rosa and Thys, 2019). It has good water- and fat- retaining properties and at the same time is a rich source of micro- and macro- elements (Biró et al., 2020).

FAO report recommends the use of insect products as they are a rich source of protein and an alternative to tackling the growing population, respectively the growing hunger.
For the European market, this type of product is exotic and in recent years has been a subject of great interest from consumers (van Huis, 2013). From 1 January 2018, in some European countries, insects, as well as parts of them, are officially authorized for production and sale, such as the so-called "novel foods" (C/2017/8878).

Replacing part of the wheat flour with crickets flour helps to reduce the total gluten content and at the same time improves the amino acid and fatty acid composition of the product (Mishyna et al., 2020). The success of the introduction of exotic foods in the menu of Europeans is associated with the added value and the shown interest that the product brings. However, the region-specific preferences, such as taste and texture, must also be taken into account (González et al., 2019). The amount of the additive should be correctly determined so that the technological and organoleptic characteristics of insect-based food are not impaired (Biró et al., 2020).

Therefore, the present study aims to determine the technological, colour and sensory characteristics of sponge cakes processed by 5 and 10% replacing wheat flour with cricket flour (*Acheta domesticus*) in order to improve its nutritional value.

### 2. Materials and methods

#### 2.1. Ingredients

Wheat flour of type 500 (WF), granulated sugar and chicken eggs were purchased from local market. Cricket flour (*Acheta domesticus*) (CF) is provided by Ento sinergy Ltd. The physicochemical parameters of the flours are presented in Table 1.

#### Table 1. Chemical composition and mineral content of wheat flour (WF) and cricket flour (CF).

#### 2.2.1. Sponge cake preparation

The cake batter was prepared (Table 2) by double mixing procedure with partitioning whipping of whites and yolks of egg (Stankov et al., 2018). The control sponge cake (WFB) formulation contained only wheat flour. In CF5B and CF10B batter the wheat flour was partially replaced with 5% and 10% CF, resp. After mixing of batter was placed in metallic pans and baked in an electric oven for 30 min at 180 °C.
2.2. Methods

2.2.1. Specific gravity (batters cakes)

The specific gravity of the sponge cake batter was calculated by dividing the weight of a batter cup to the weight of an equal volume of distilled water (AACC 10-95, 1983).

2.2.2. Colour characteristics

A Konica Minolta colorimeter CR-410 (Konica Minolta Holding, Inc., Ewing, New Jersey, USA) was used to evaluate the brightness (L* value), the red component (a* value) and the yellow component (b* value) (Hunt et al. 2012). Total colour difference (ΔE) is calculated:

\[ \Delta E = \sqrt{\Delta L^2 + \Delta a^2 + \Delta b^2}, \]

where \( \Delta L^* \), \( \Delta a^* \) and \( \Delta b^* \) are the differences in the values of \( L^* \), \( a^* \), \( b^* \) between those of the control and the corresponding experimental sample.

2.2.3. pH value determination

The pH value of the samples was measured electropotentiometrically (Osimani et al., 2018) with pH meter "Microsyst MS 2004" (Microsyst, Plovdiv), equipped with temperature and combined pH electrode. The pH electrode is of the Sensorex Combination Recorder S 450 CD type (Sensorex pH Electrode Station, Garden Grove, CA, USA).

2.2.4. World photographic analysis

Sample analysis was performed using a microscope (Olympus BX41TF, Japan) at a magnification of 100x.

2.2.5. Determination of volume of the product

Volume was measured by the small, homogeneous grain displacement method with a volume meter, [cm³] (Ngo et al., 1986; AACC 10-05, 2000);

2.2.6. Determination of specific volume

It is calculated by the ratio of the volume of the cake to its mass, [cm³ / g];

2.2.7. Structural and mechanical properties of cakes

Shrinkage [PU] and springness (relaxation) [PU] are determined with an automatic penetrometer (model DS VEB Feinmess, Dresden, Germany) (Stankov et al., 2018).

2.2.8. Water activity (aw)

The water activity of the batter and the crumb samples was determined using a Novasina AG CH-8853 water activity meter (Zurich, Switzerland) at 20 °C.

2.2.9. Moisture content

The moisture content is determined after drying the sample at 104 - 105 °C till reaching a constant weight AACC 44-15.02. (AACC, 1999).

2.2.10. Water absorption capacity

The water absorption capacity of the cake was measured by the method for determining of biscuits’ swelling according to BDS 15221: 1981.

2.2.11. Sensory evaluation

Five member panel group with proven abilities was used to determine the sensory parameters (appearance, cell size uniformity, crumb tenderness, odour and taste) of the cakes (Meilgaard et al. 1999) was used. The samples were scored using 1 to 5 scales.

For the determination of the sponge cake crumb structure, photographs were taken of the half-cut cake.

### 2.2.13. Statistical analysis

Statistical analysis of the average values of five time reps was made. All statistical procedures for the data of different samples were analyzed by SAS software (SAS Institute, Inc. 1990). The Student-Newman-Keuls multiple range test was used to compare differences among means. The results were expressed as mean values and standard errors of the mean. A p-value less than 0.05 (p < 0.05) was considered as significant.

### 3. Results and discussions

#### 3.1. Physicochemical characteristics

As a result, the water activity of the sponge system correlates to the forms of the bound water. By the slightly acidic reaction of CF, pH in batter decrease with the increase in CF concentration (10%, CF_{10}B) (Table 3). According to Osimani et al., 2018 the higher ash content of CF influences the buffering capacity in the matrix and decrease the pH of batter (Mariotti et al., 2014; Taccari et al., 2016).

With increasing the amount of CF, the moisture content (Table 3) decreases both in the batter and the cakes (p ≤ 0.05). At the same time, the highest value (p ≤ 0.05) for water activity (a_{w}) was found in the WFB control samples. Water activity (a_{w}) of control batter (WFB) was 1.63 (p ≤ 0.05) and 2.17% (p ≤ 0.05) higher than the samples with 5 and 10% addition of cricket flour (CF_{5}B and CF_{10}B), respectively. The data confirmed previous researches proving that lower water activity result in higher moisture loss (Indriani, 2020). Another possible reason for the established decrease of a_{w} is the lower moisture content of blended with 5% and 10% CF flour used for preparing the CF_{5}B and CF_{10}B sponge cakes.

WFB, cake batter containing 100% wheat flour; CF_{5}B – cake batter with blend containing 5% cricket flour and 95% wheat flour; CF_{10}B – cake batter with blend containing 10% cricket flour and 90% wheat flour; WFC – sponge cake containing 100% wheat flour; CF_{5}C, sponge cake with blend containing 5% cricket flour and 95% wheat flour; CF_{10}C- sponge cake with blend containing 10% cricket flour and 90% wheat flour.

Results are presented as Means ± Standard error of the means (SEM)

\[^{1}\text{PU - Penetrometer Units.}\]

\[^{a,b,c}\text{Means with different superscripts in each column differ significantly (p ≤ 0.05) of one parameter}\]

3.2. Textural parameters

The quality of sponge cakes is determined by their baking properties (Table 3). An increase in the relative mass by decrease in the degree of aeration was found in CF enriched cakes (p ≤ 0.05). The highest degree of shrinkage and springiness characterized the control (WFB) with the highest degree of softness. The CF_{5}C specific volume, shrinkage
and springiness are lower \((p \leq 0.05)\), but close to those obtained for WFC. Decreased springiness and more difficult chewing have also been reported by Pauter et al., 2018 in sponge cakes with CF. The mass and bulk between controls (WFB) and CF\(_5\)B do not differ significant \((p \leq 0.05)\). The data obtained for specific volume (Table 3) did not show a statistically significant \((p \leq 0.05)\) difference between the two CF based sponge cakes (CF\(_5\)C and CF\(_{10}\)C). Compared to WFC, the specific volume in CF\(_5\)C and CF\(_{10}\)C is about 5\% \((p \leq 0.05)\) lower, which is most likely due to the higher protein content and the lower degree of aeration of the batter. In contrast to our results, González et al., (2019) replaced 5\% WF with grounded *Hermetia illucens*, *Acheta domestica*, *Tenebrio molitor* protein and fibre and did not report changes in specific volume in bread. Perhaps the presence of fibre in recipe composition helps to preserve the specific volume and texture of the product.

The deterioration of the parameters relative mass, springiness, shrinkage and specific volume increases with higher amount of CF \((p \geq 0.05)\). The shrinkage determines the internal stability of the structure, as it is directly related to the ingredients used in making the batter.

The exact amount of insect flour is very important. According to Indriani et al. (2020) the starch content is lower in the cakes after wheat replacement. On the other hand, cricket exoskeleton contained 8-9\% non-soluble chitin, which is a source of insoluble fibre. Chitin makes foam bubbles unstable and decrease film layer stability. Poor foam properties of CF (*Acheta domestica*) were reported by Yi et al., (2013). A linear correlation between volume, hardness and insect flour used for processing of cinereous cockroach (*Nauphoeta cinerea*) enriched breads was proven by de Oliveira et al. (2017). The results obtained show that the replacement of WF with CF in an amount of up to 5\% has a lower impact on the technological characteristics of sponge cakes.

### 3.3. Colour characteristics

Blending the wheat flour with cricket flour affected the cake lightness \((p \leq 0.05)\). The batter colour lightness \((L^*)\) \((WFB)\) was 7.11\% and 10.51\% higher than that measured after the partial replacement with CP \((p \leq 0.05)\). The same trend was established after baking. The \(L^*\) value of WFC was 8.24 and 12.56\% higher \((p \leq 0.05)\), compared to the cakes with 5 and 10\% cricket flour, respectively (Table 4).

WFB, cake batter containing 100\% wheat flour; CF\(_5\)B – cake batter with blend containing 5\% cricket flour and 95\% wheat flour; CF\(_{10}\)B – cake batter with blend containing 10\% cricket flour and 90\% wheat flour; WFC – sponge cake containing 100\% wheat flour; CF\(_5\)C, sponge cake with blend containing 5\% cricket flour and 95\% wheat flour; CF\(_{10}\)C- sponge cake with blend containing 10\% cricket flour and 90\% wheat flour. Results are presented as Means ± Standard error of the means (SEM)

\(a,b,c\) Means with different superscripts in each column differ significantly \((p \leq 0.05)\) of one parameter.
The control sponge cakes (WFC) was lowest in colour redness (a*) (p ≤ 0.05) and highest in yellow colour component (b*) (p ≤ 0.05). Both in the batter and in the baked cakes a* increases and b* decreases with higher CF replacement (p ≤ 0.05). In a similar study of muffins with 5 and 10% CF a* and b* values shifted to the green and blue areas, respectively (Pauter et al., 2018).

When using ingredient for wheat replacement, it is desirable for products to retain their colour characteristics in order to be accepted by the consumers (Biró et al., 2020). The darker colour in CF based cakes is expected, as the cricket flour is darker in colour, too. Decreases in L* values were also obtained in other studies after partial replacement of WF with CF in muffins (Pauter et al., 2018), cricket-Enriched Oat Biscuit (Biró et al., 2020) and in other cricket-based foods (Mishyna et al., 2020). We can conclude that blending the WP with CF should not exceed 5% in order to avoid the colour deterioration of the final product.

It’s reported that deviation in ΔE above 3.5 is a proof for significant difference between two samples (Tkacz et al., 2020). Total colour difference (ΔE) of CF_{10}C is 33% higher compared to ΔE of CF_{5}C. We can conclude that the replacement of WP with CF significantly changes the total colour difference (ΔE) in a dose-dependent manner (p ≤ 0.05).

3.4. Sensory analysis

The results of the sensory analysis confirm the data for the relative mass of the batter. The sensory panel also confirms the data on the specific volume of cricket-based cakes, which decreases with increasing amount of CF. It is known that usage of edible insects with hard exoskeletons (crickets, grasshoppers) containing chitin, result in insect based products with soft texture. Even more, the legs and wings of grasshoppers and locusts should be removed before consumption (van Huis et al., 2013). Microscopic photographs of the batter clearly show the presence of solid particles from the chitin shells (Fig.1).

The high dry matter content and the correspondingly lower humidity of CF cakes are another reason for their drier texture.

The best evaluated in terms of appearance, cell size uniformity, crumb tenderness, odour and taste is the control sample (WFC) followed by 5% cricket-enriched cakes (Fig. 2). Sensory analysis showed that the colour of the outer surface of WFC, CF_{5}C and CF_{10}C after baking did not differ statistically significantly, but the cell size uniformity darkened with increasing % of CF replacement. These results are in sync with the colour lightness data (L*) (Table 4).

<table>
<thead>
<tr>
<th>Control sample (WFC)</th>
<th>Sponge cake (CF_{5}C)</th>
<th>Sponge cake (CF_{10}C)</th>
</tr>
</thead>
</table>

WFC – sponge cake containing 100% wheat flour; CF_{5}C, sponge cake with blend containing 5% cricket flour and 95% wheat flour; CF_{10}C- sponge cake with blend containing 10% cricket flour and 90% wheat flour.

Figure 1. Photographs of cross sections of the sponge cakes, and micro photograms of batters.
After partial replacement of WP with 10% CF, the cakes (CF10C) have a visibly smaller volume (Table 3).

The most significant changes were found in the texture of CF10C blended sponge cakes. The results of the sensory analysis were in sync with the data obtained for shrinkage and springiness of the cakes (Table 3). The texture of cricket-based cakes was denser, with an increase in chewing hardness correlated with the amount of CF used. The sensory panel rated CF10C as too dry. A drier consistency has also been reported by Pauter et al., 2018 when adding CF to cakes. According to Kinyuru, Kenji, & Njorge (2009), replacing WP with ground termite up to 5% does not affect the texture of the products. Apart from the amount, probably the type of insect flour used is another factor determining the maximum percentage used in the product. Although cricket flour does not have a strong specific aroma, CF10C sponge cakes have an uncharacteristic aftertaste, which is the reason for the low taste and smell grades given to CF10C.

4. Conclusions

The high nutritional value of edible insects and the interest to that exotic alternative protein source played the attention of food industry as potential food ingredient. Quality characteristics of cricket flour labelled sponge cakes were strongly influenced by CF concentration. Replacement of wheat flour with 5% cricket flour had slight effect on the sensory properties of sponge cakes. Replacement with 10% cricket flour showed negative effect on colour characteristics with highest decrease in L* and a* value, as well as increase in b* value. The shrinkage, springiness and texture characteristics of cakes correlate with CF concentration and decreased significantly in 10% CF based sponge cakes. pH, moisture and a_w decreased in CF blended cakes in a dose-dependent manner. In accordance to the sensory and textural characteristics of CF labelled sponge cakes the cricket flour can successfully be used up to 5% as WF substitute as innovative ingredient to enhance the nutritional value in baked products.
